Ligand Displacement

displacement reaction.

In coordination chemistry, ligands can be exchanged through a ligand $[Co(OH_2)_6]^{2+} + 6NH_3 \rightleftharpoons [Co(NH_3)_6]^{2+} + 6H_2O$

Stepwise Displacement

- Step #1: $[Co(OH_2)_6]^{2+}(aq) + NH_3(aq) \Rightarrow [Co(OH_2)_5NH_3]^{2+}(aq) + H_2O(l)$
- Step #2: $[Co(OH_2)_5 NH_3]^{2+} (aq) + NH_3 (aq) \Rightarrow [Co(OH_2)_4 (NH_3)_2]^{2+} (aq) + H_2O(l)$
- Step #3: $[Co(OH_2)_4(NH_3)_2]^{2+}(aq) + NH_3(aq) \Rightarrow [Co(OH_2)_3(NH_3)_3]^{2+}(aq) + H_2O(l)$
- Step #4: $[Co(OH_2)_3(NH_3)_3]^{2+}(aq) + NH_3(aq) \Rightarrow [Co(OH_2)_2(NH_3)_4]^{2+}(aq) + H_2O(l)^{2+}(aq) + H_2O(l)^{2+}(aq) + H_2O(l)^{2+}(aq) + H_2O(l)^{2+}(aq)^{2+}($
- Step #5: $[Co(OH_2)_2(NH_3)_4]^{2+}(aq) + NH_3(aq) \rightleftharpoons [Co(OH_2)(NH_3)_5]^{2+}(aq) + H_2O(l)$
- Step #6: $[Co(OH_2)_1(NH_3)_5]^{2+} aq) + NH_3(aq) \Rightarrow [Co(NH_3)_6]^{2+} (aq) + H_2O(l)$

Example

Step #1: $[Co(OH_2)_6]^{2+}$ (aq) + NH₃ (aq) \Rightarrow $[Co(OH_2)_5NH_3]^{2+}$ (aq) + H₂O (I)

What is K_{eq} for step 1?

Example

108

$[M(OH_2)_6]^{z+}(aq) + 6L(aq) \rightleftharpoons [ML_6]^{z+}(aq) + 6H_2O(I)$

$K = \frac{[ML_6^{z+}]}{[M(OH_2)_6^{z+}][L]^6}$

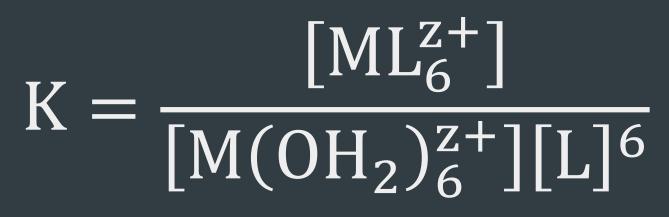

Trends in Equilibrium Constants

log K

$[M(OH_2)_6]^{z+}(aq) + 6L(aq) \rightleftharpoons [ML_6]^{z+}(aq) + 6H_2O(I)$

Number of Displaced H₂O Ligands

Enthalpy and Entropy in Complex Formation

When complex formation occurs (going from free metal cation and ligands) to a ML₆ complex), the changes in enthalpy for these processes are significantly negative.

However, this change is accompanied by a significantly negative change in entropy.

Enthalpy and Entropy in Exchange

When ligand exchange occurs depending on the enthalpy change may be positive or negative. It depends on the relative bond strengths and solvation enthalpy of the ligands.

However, this change is accompanied by a significantly positive change in entropy (at least for the first few steps).

Complex Stability

Factor 1: Ionic size and magnitude of the charges.

The stability of a complex with a specific ligand increases substantially as the ionic charge increases. That is electrostatics predicts that bond strength should increase with the charge density of the cation.

This is only true if orbital interactions and polarizability can be ignored (very ionic compounds)

Complex Stability

and ligands (e⁻ donor / Lewis base).

Hard acids (hard metal cations) form more stable complexes with hard bases (hard ligands).

Soft acids (soft metal cations) show a preference for soft bases (soft ligands).

Factor 2: Stability of the complex depends on the parity of orbital radius and magnitude of orbital overlap between metal ion (e- acceptor / Lewis acid) the

Hard vs. Soft Acids (metals)

Hard acids have high charge densities and small valence orbitals Not very polarizable Attracted to ligands that are not very polarizable • Examples: Cr^{3+} , Zr^{4+} , Al^{3+}

Soft acids are prototypically large cations with low charge densities Very polarizable Interact with ligands that are also very polarizable Examples: Cu⁺, Ag⁺, Au⁺

Hard vs. Soft Bases (ligands)

Hard/Soft Ligands are categorized by their electronegativities and polarizability

Hard Ligands

Ligand oxidation state / hybridization can lead to very different 'hardness'

$F > O > N > CI > Br > C \approx I \approx S > Se > P > As > Sb$

Ammonia vs Nitride

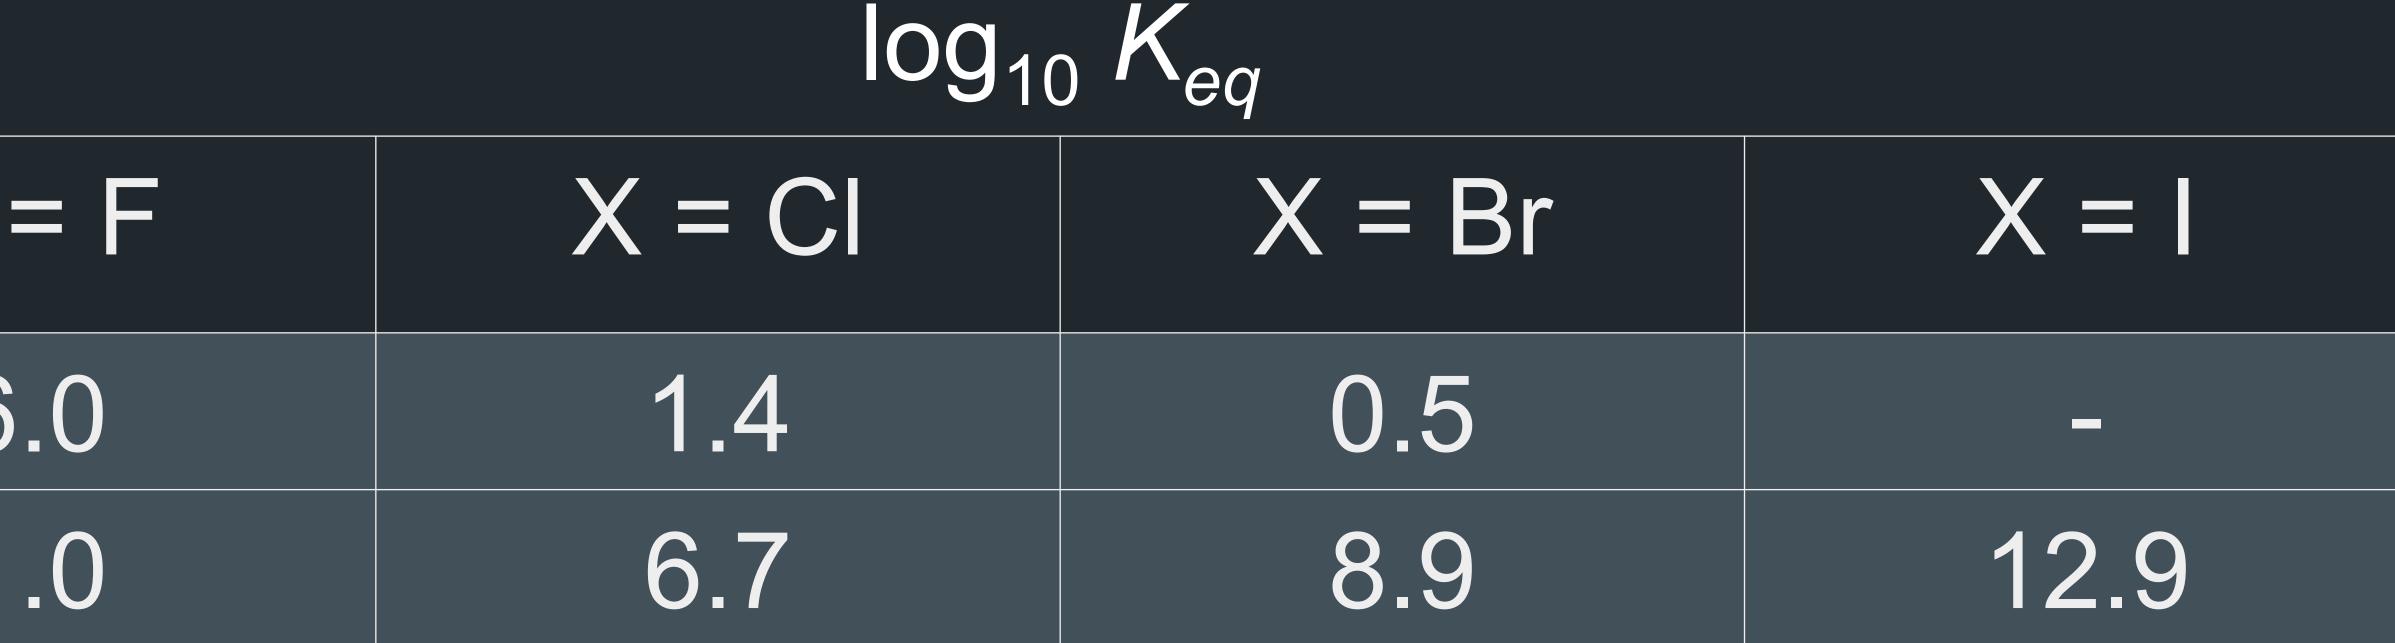

Soft Ligands

Example

$Fe^{3+}(aq) + X^{-}(aq) \rightleftharpoons [FeX]^{2+}(aq)$

Metal Ion	
	X
Fe ³⁺	6
Hg ²⁺	

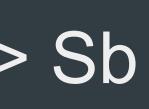

$F > O > N > C| > Br > C \approx | \approx S > Se > P > As > Sb$

(Hard to Soft Ligands)

 $Hg^{2+}(aq) + X^{-}(aq) \rightleftharpoons [HgX]^{+}(aq)$

General Trends

with light cations and high charge.

- s-block: Na⁺, Mg²⁺
- p-block: Al³⁺
- d-block: Sc³⁺, Cr³⁺, Fe³⁺
- *f*-block: Ce³⁺, Th⁴⁺

important driving force. p-block: TI+ • d-block: Cu⁺, Ag⁺, Hg²⁺

Ligands with hard donor atoms (e.g. O and N) form more stable complexes

Ligands with soft donor atoms (e.g. S and P) show a preference for heavy metal ions and small charge. Mutual polarization and covalence is a more

Common Ligands & Metals

Hard

F⁻, Cl⁻, H₂O, alcohols, ethers, OH⁻, alkoxide, carboxylate, CO_3^{2-} , NO_3^{-} , PO_4^{-} , SO_4^{2-} , CIO_4^{-} , oxalate, NH_3 , & organic amines

Soft

I-, H-, alkyl anion (R:-), CN-, CO, isocyanide (R-NC), thiol (R-SH), thioethers (RSR), thiolate (R–S⁻), thiocyanate (-SCN), phosphines R₃P, arsines R₃As, Stibene R₃Sb, alkene, arene

Intermediate

Br⁻, N₃⁻, pyridine, aniline (Ph-NH₂), NO₂⁻, $\& SO_{3}^{2-}$

Ligands

TI³⁺

Pb²⁺, Fe²⁺, Co²⁺, Ni²⁺, Cu²⁺, Os²⁺, Ru³⁺, Rh³⁺, & Ir³⁺

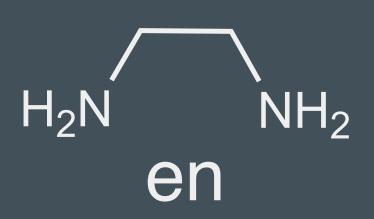

Metals

Li⁺, Na⁺, K⁺, Rb⁺, Be²⁺, Mg²⁺, Ca²⁺, Sr²⁺, Sn²⁺, Mn²⁺, Zn²⁺, Al³⁺, Ga³⁺, In³⁺, Sc³⁺, Cr³⁺, Fe³⁺, Co³⁺, Y³⁺, Th⁴⁺, Pu⁴⁺, Ti⁴⁺, Zr⁴⁺, [VO]⁺, & $[VO_{2}]^{+}$

Al, Cu, Zn, Ga, Cr, Fe, Hg, Ag, Au, Tl⁺, Cu⁺, Ag+, Au+, [Hg₂]+, Hg²⁺, Cd²⁺, Pd²⁺, Pt²⁺, &

Bidentate Ligands

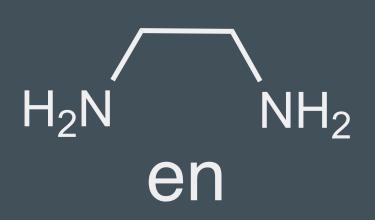

$[Ni(OH_2)_4(NH_3)_2]^{2+}(aq) + en(aq) \rightleftharpoons [Ni(OH_2)_4(en)]^{2+}(aq) + 2NH_3(l) \quad K_{eq} = 257$

Example – two eqiv. of ethylenediamine (en)

$[Ni(OH_2)_2(NH_3)_4]^{2+}(aq) + 2 en (aq) \rightleftharpoons [Ni(OH_2)_2(en)_2]^{2+}(aq) + 4NH_3(l) K_{eq} = 5.2 \times 10^5$

Example

$[Ni(NH_3)_6]^{2+}(aq) + 3 en (aq) \rightleftharpoons [Ni(en)_3]^{2+}(aq) + 6 NH_3 (/)$

$K = 1.9 \times 10^9$

Entropy and K

$[Ni(OH_2)_4(NH_3)_2]^{2+}(aq) + en(aq) \rightleftharpoons [Ni(OH_2)_4(en)]^{2+}(aq) + 2NH_3(l)$

$[Ni(OH_2)_2(NH_3)_4]^{2+}(aq) + 2 en (aq) \rightleftharpoons [Ni(OH_2)_2(en)_2]^{2+}(aq) + 4NH_3(l)$

$[Ni(NH_3)_6]^{2+}(aq) + 3 en (aq) \Rightarrow [Ni(en)_3]^{2+}(aq) + 6NH_3(l)$

K = 257

$K = 5.2 \times 10^{5}$

$K = 1.9 \times 10^9$

Chelate Effect

the chelate effect.

 $[Ni(OH_2)_4(NH_3)_2]^{2+}(aq) + en(aq) \rightleftharpoons [Ni(OH_2)_4(en)]^{2+}(aq) + 2NH_3(l)$

A chelate more thermodynamically stable than that of a complex containing a corresponding number of comparable monodentate ligands. This is called

K = 257

Stability Theories That Help Explain the Chelate Effect

Entropy driven: $\Delta G = \Delta H - T \Delta S$ 1.

Other factors to consider:

- 2. monodentate ligands to one bidentate ligand.
- the solvent
- 5.

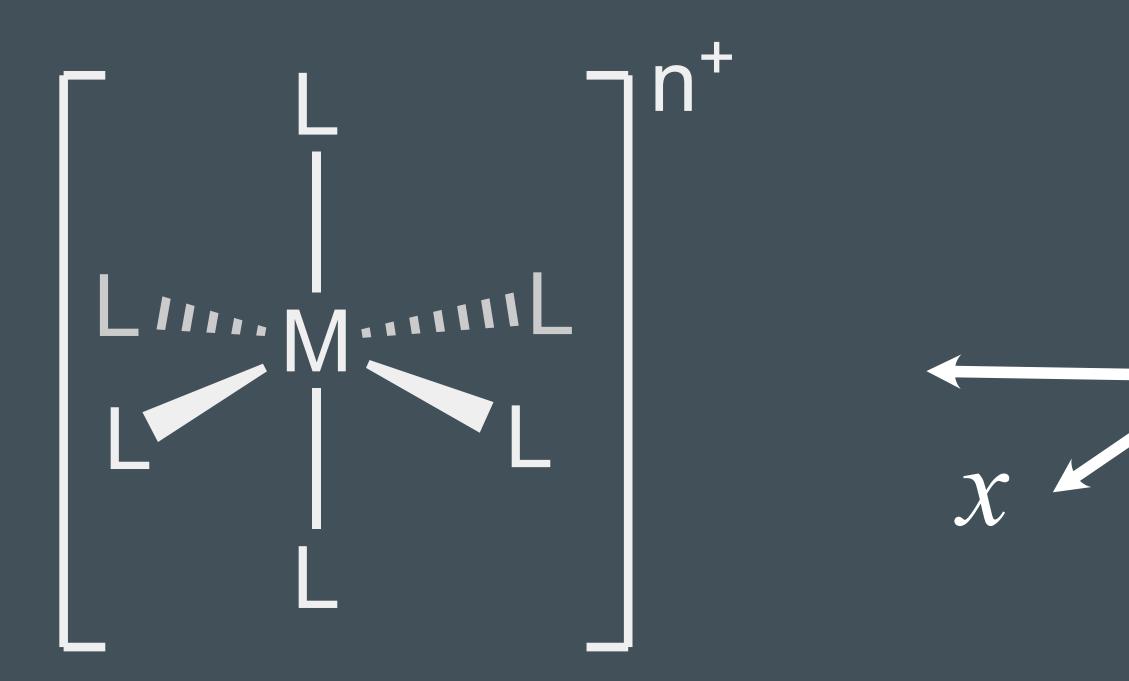

A reduction in the electrostatic repulsion between the donor atoms going from two

3. Desolvation effects involving the disruption of hydrogen bonds between the water ligand and

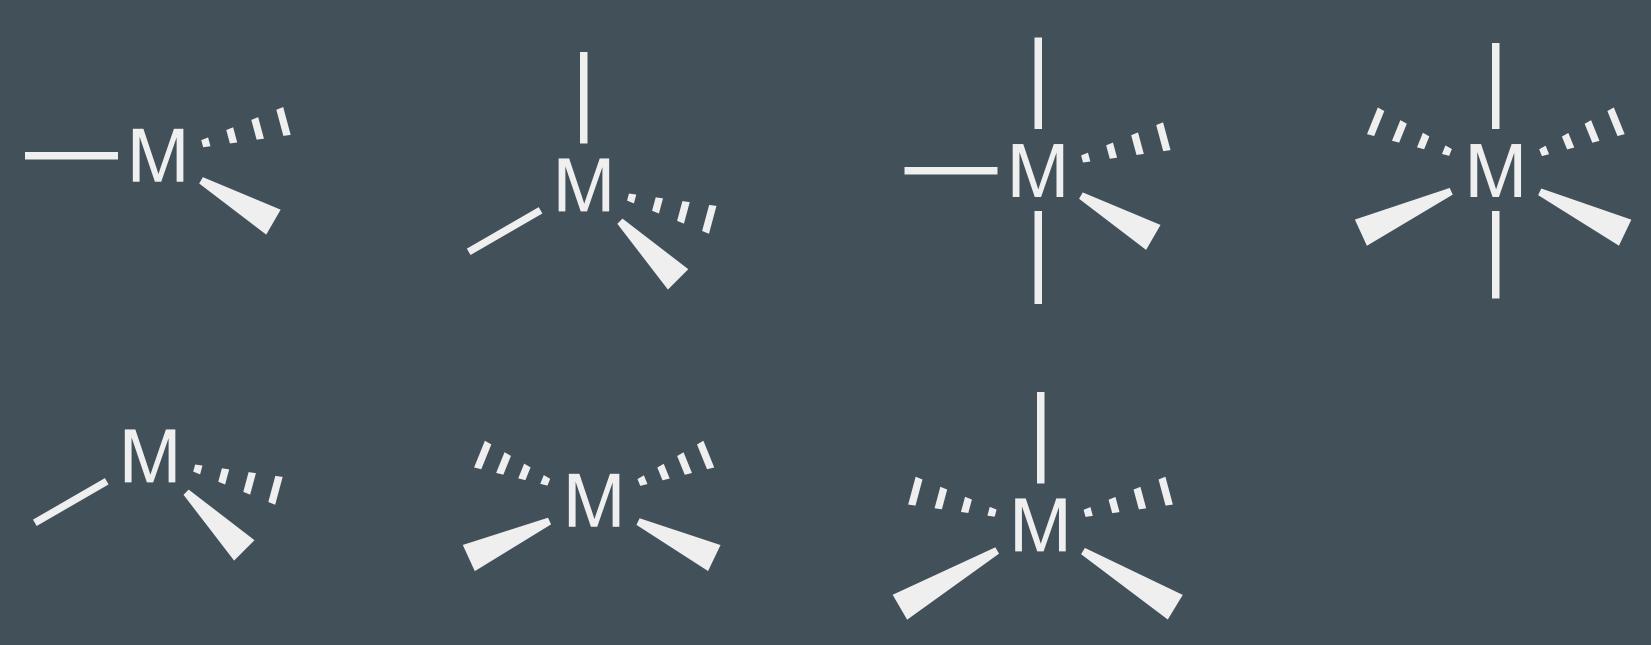

4. An inductive effect of the backbone bridges in polydentate ligands which increase the donor strength of the ligand with respect to a corresponding monodentate ligand

A proximity effect. The after one part of bidentate ligand binds the other donor is statistically much closer to the metal then any other free monodentate ligand in solution. Thus it is more likely to interact and coordinated to the metal center.

3-D Shape of Complexes

We'll focus on the octahedral coordination geometries

d-orbitals Review

For $\ell = 2$, there are only five degenerate harmonics that satisfy the Schrödinger equation:

These are complex functions. However, using the principal of superposition we can take linear combinations of these m_{ℓ} wavefunctions (physics) to get a set of 5 other wavefunctions that evaluate as purely real numbers. These are:

The 5 chemistry d-orbitals: d_{xy} , d_{yz} , d_{xz} , $d_{x^2-y^2}$, and d_{z^2}

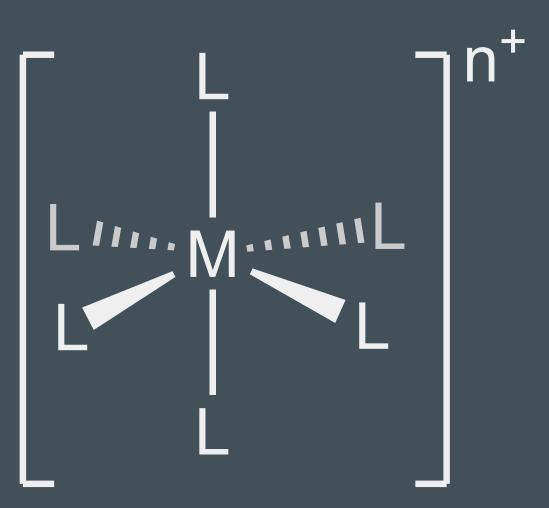

d-orbitals are characterized by the quantum number $\ell = 2$

 $m_{\ell} = +2, +1, 0, -1, -2$

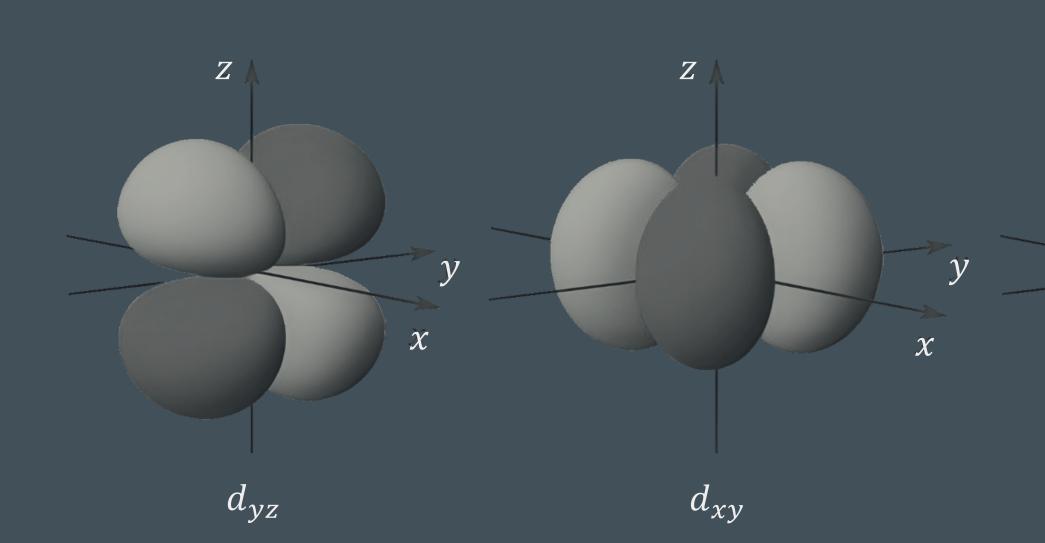

Plotting and drawing the d-orbitals

3D Render

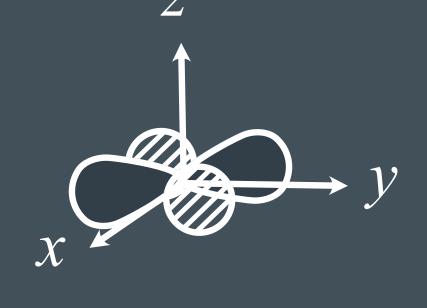

Drawing them by hand

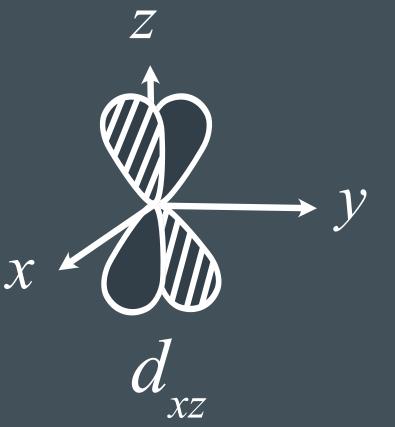

Take carful note of the orientations with respect the the axes! 128

 $d_{x^2 - y^2}$

The d_{z^2} -orbital looks different

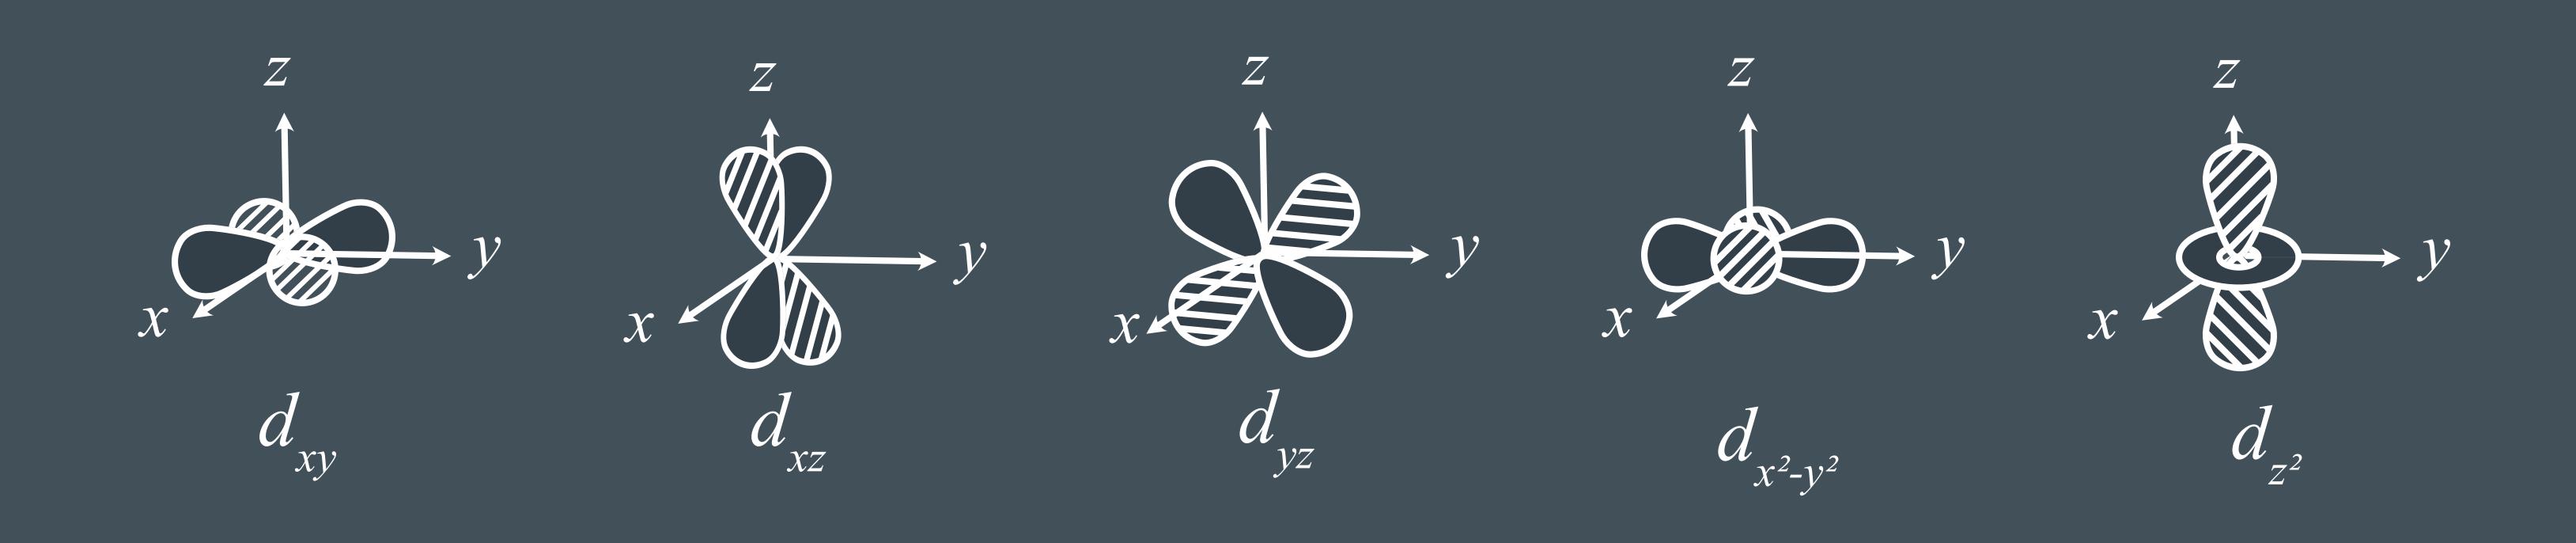

This is <u>not</u> a *p*-orbital!

Orbital Notation for *d*-orbitals

Recall: Transition metals don't necessarily follow strict electron count rules like the octet rule for carbon. They are more complicated!

Odd electron counts and unpaired electrons in even electron counts are common!

Basics of Magnetism – Unpaired electrons

Magnetic data for d⁶ octahedral complexes show that there are two main categories.

1. Paramagnetic: complexes with at least one unpaired electron

2. Diamagnetic: complexes with no unpaired electrons

Example

Experimental data also suggests that there are two magnetic categories for d^4 , d^5 , and d^7 octahedral complexes.

Unlike d^6 , these complexes are ALL paramagnetic. The only difference is that they have a different number of unpaired electrons.
